# Tables in an open space office

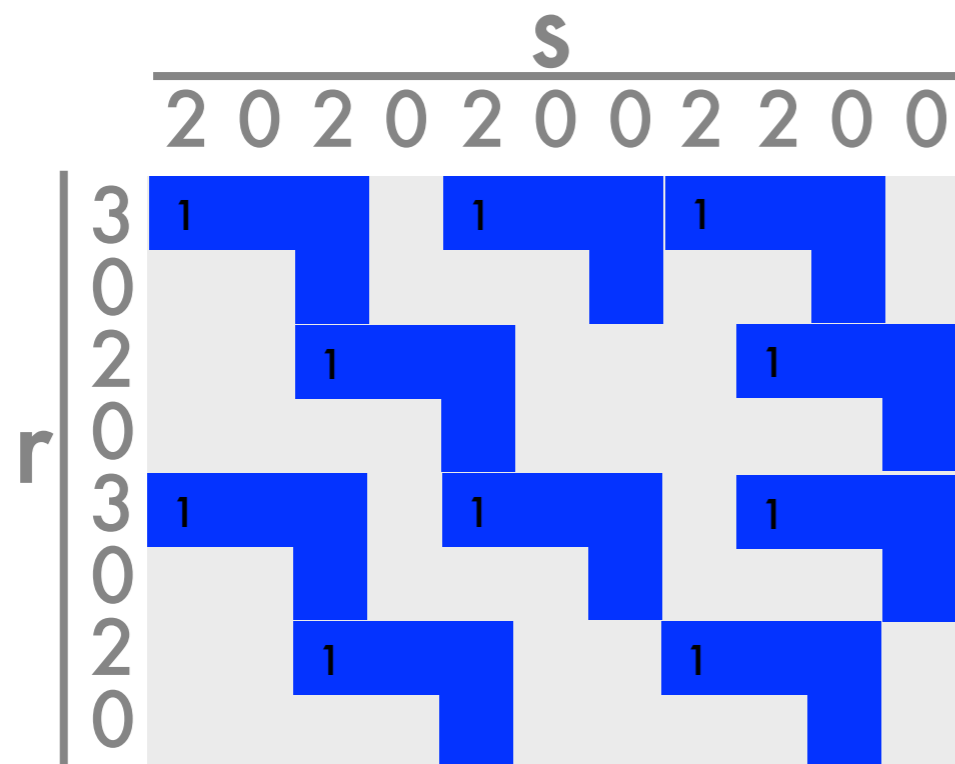

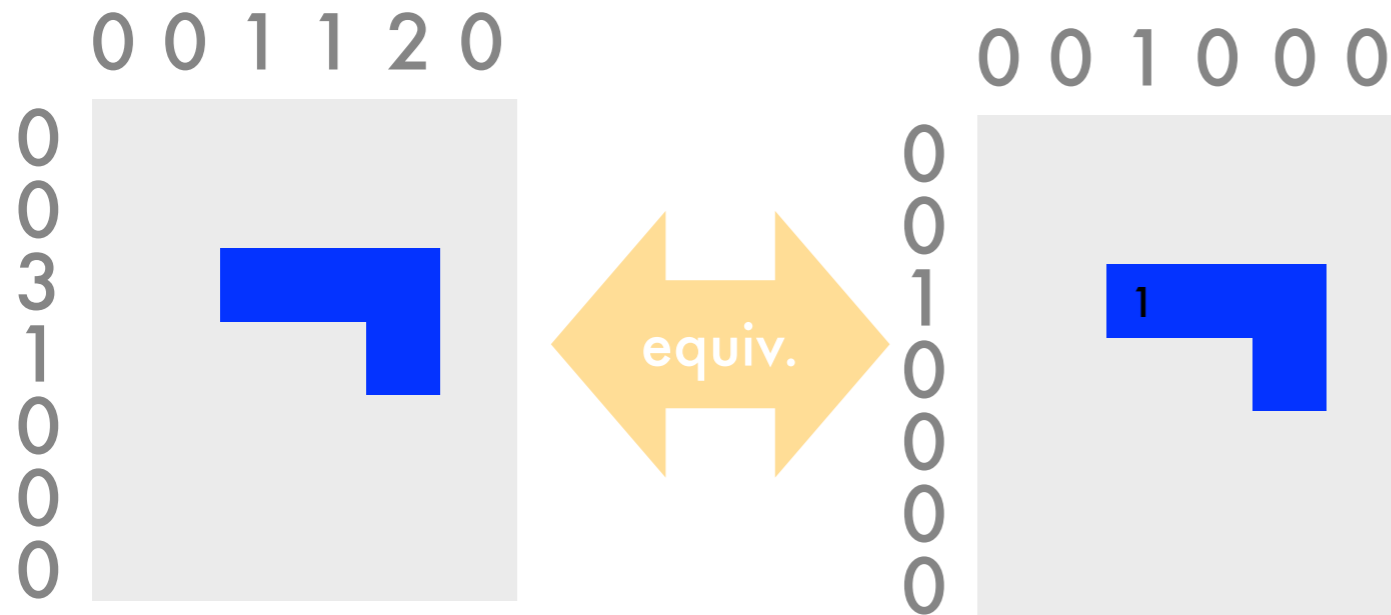

- disjoint copies of the same shape
- same orientation

# Non-intrusive measurement

- the office is an  $n \times m$  grid
- tables are aligned on the grid
- Measurement results in projection vectors  $r, s$
- such that  $r_i$  is the number of grid cells of row  $i$  covered by a table (tile)
- same for columns

# Equivalent measurement

- alternative measurement (equivalent up to base change) :
- mark a cell in the tile
- projections count only marks

# The tiling reconstruction pb

- A tile is a connected set of grid points
- Given a tile  $T$ , dimensions  $n,m$  and projections  $r, s$
- does there exist a binary matrix  $M$
- with  $r_i = \sum_j M_{ij}$ ,  $s_j = \sum_i M_{ij}$
- and for  $M_{ij}=1, M_{i'j'}=1$ , the tiles  $T+(i,j)$  and  $T+(i',j')$  are disjoint ?

		$s$

- and for  $M_{ij}=1, M_{i'j'}=1$ , the tiles  $T+(i, j)$  and  $T+(i', j')$  are disjoint?

# Complexity depends on T

- When the tile T is a bar, the problem is polynomial

- [Ryser'63] Characterize  $r, c$  such that there is a binary matrix with projections  $r, c$

- [Picouleau'01] [D,Goles,Rapaport,Rémila'03] greedy algorithm to reconstruct tilings with bars

- [this paper] When the tile T is not a bar, the problem is NP-hard

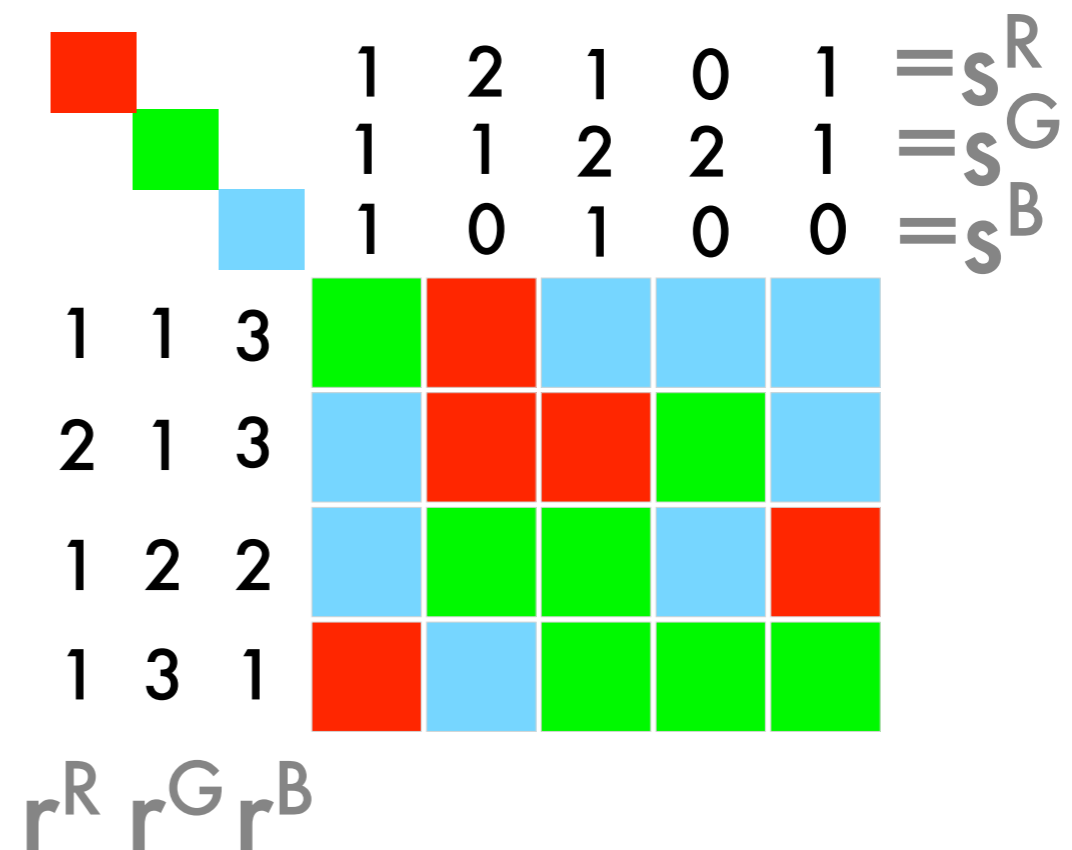

- [Chrobak,Couperous,D, Woeginger'03] NP-hardness for some very specific tiles

# Related : 3-color tomography

- 3 colors  $\{R,G,B\}$
- given projections  $r^c, s^c$   
for every  $c \in \{R,G,B\}$
- is there a matrix  $M \in \{R,G,B\}^{n \times m}$
- such that  $r^c_i = \#\{j: M_{ij}=c\}$   
and  $s^c_j = \#\{i: M_{ij}=c\}$   
for every  $c \in \{R,G,B\}$

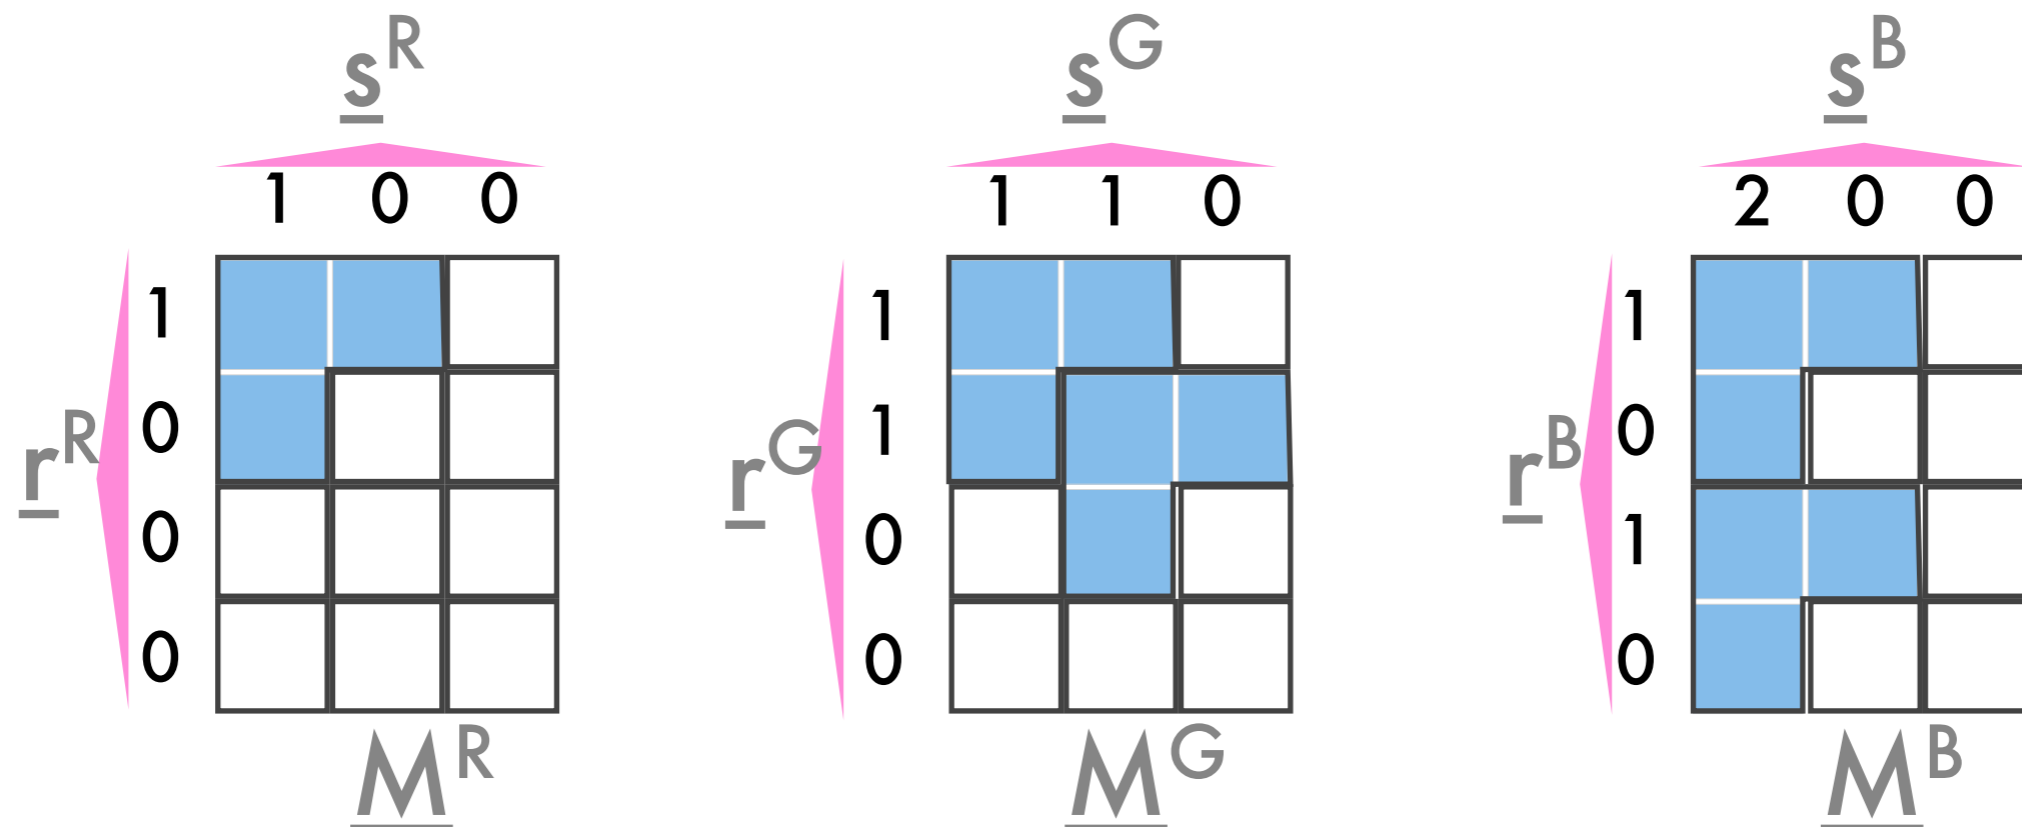

- [D,Guíñez,Matamala'09]  
3-color tomography is NP-hard

# Reduction from 3-color tomography

- Reduce from 3-color tomography to tiling tomography

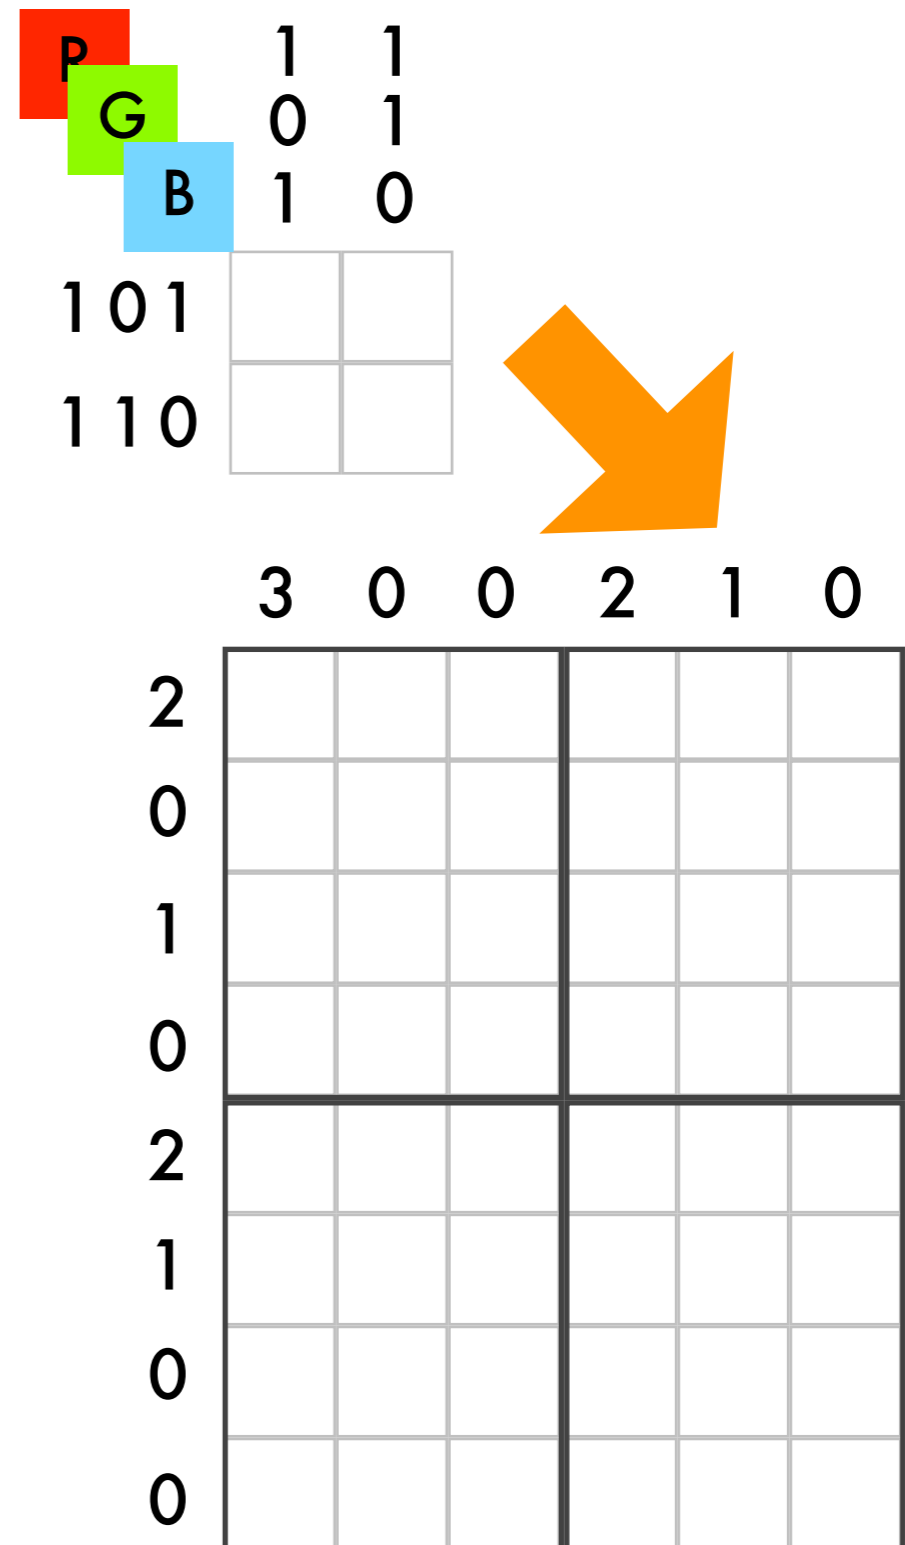

- Choose a block of fixed dimension  $k \times l$
- Choose 3 tilings of the block

# Reduction from 3-color tomography

- [in] instance  $r^c, s^c$  ( $c \in \{R, G, B\}$ ) of the 3-color tomography problem for an  $n \times m$  grid
- [out] instance  $r, s$  of the tiling tomography problem for an  $n_k \times m_l$  grid such that projections of block row  $i$  are  $r_i^R \cdot \underline{r}^R + r_i^G \cdot \underline{r}^G + r_i^Y \cdot \underline{r}^Y$  (same for columns)

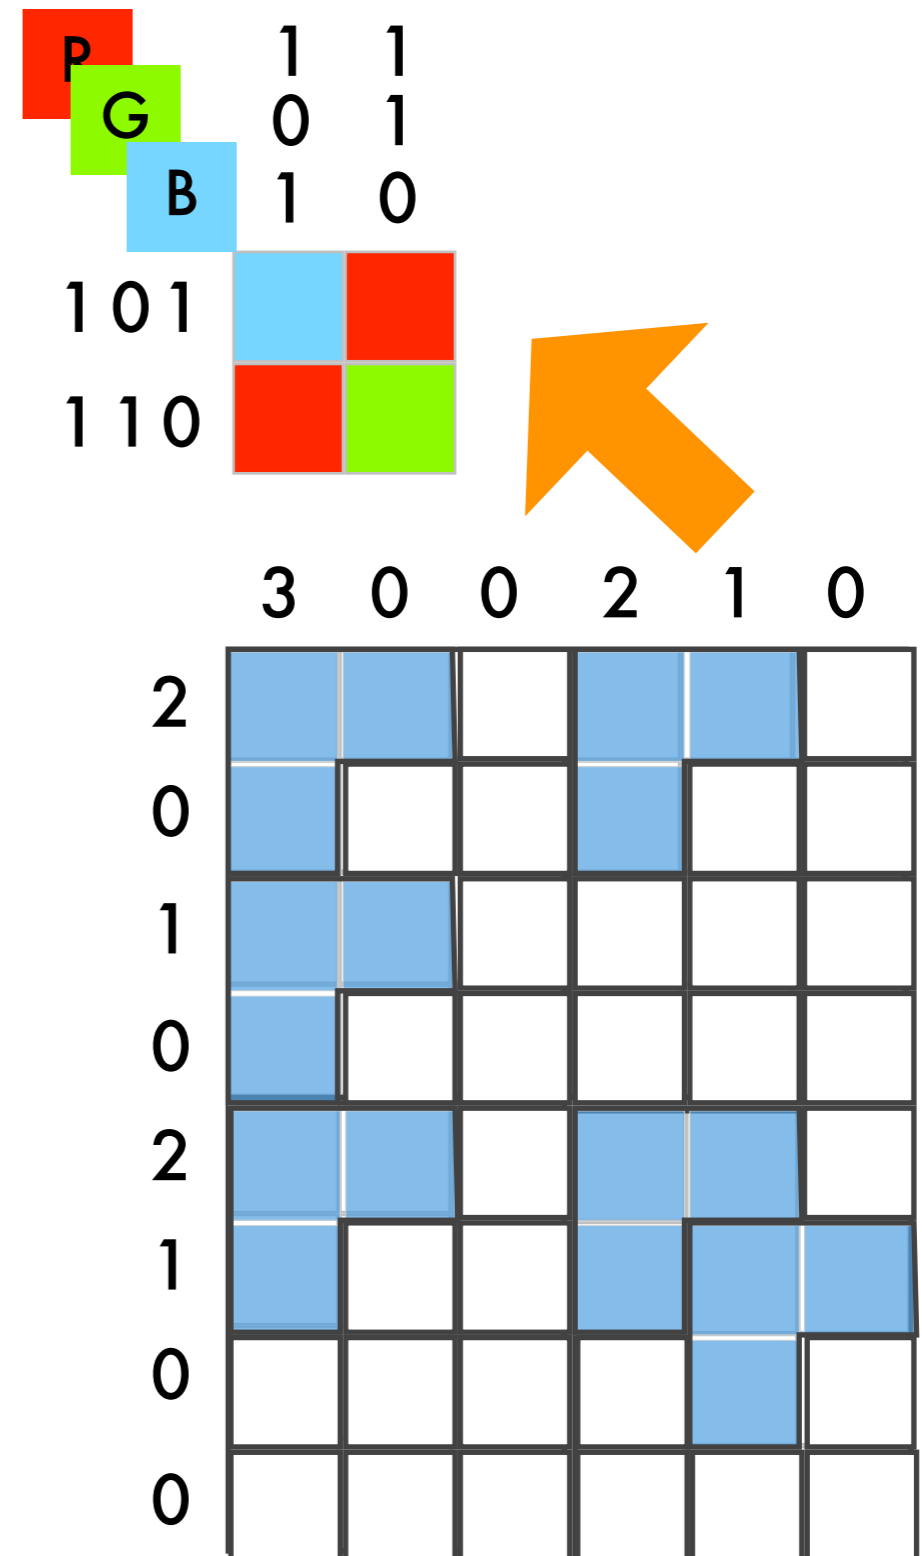

# Requirements

- (R1) the row projections  $\underline{r}^R, \underline{r}^G, \underline{r}^Y$  have to be affine linear independent
- (R2) Let  $M$  be a solution to the tiling tomography instance obtained by the reduction. Then every block in  $M$  is one of  $\underline{M}^R, \underline{M}^G, \underline{M}^Y$  (or projection-equivalent)

# Implications

- (R2)  $\Rightarrow$  we can associate a color to every block in  $M$
- and replace every block by a single colored cell (contract)
- (R1)  $\Rightarrow$  the obtained grid has the required projections, since any vector  $n_R \cdot \underline{r}^R + n_G \cdot \underline{r}^G + n_Y \cdot \underline{r}^Y$  for  $n_R + n_G + n_Y = n$  is uniquely decomposed into  $n_R, n_G, n_Y$ .

# Apply this technique

- We divide the tiles into four classes
- and have a different construction for every class
- Fix a maximal conflicting vector  $(p,q)$
- Choose smallest  $a > 0$  such that  $(ap, 0)$  is not conflicting
- Choose smallest  $b > 0$  such that  $(0, bq)$  is not conflicting
- Cases are broken according to  $a, b, p, q$

$$(p,q)=(1,3)$$

$$b=1$$

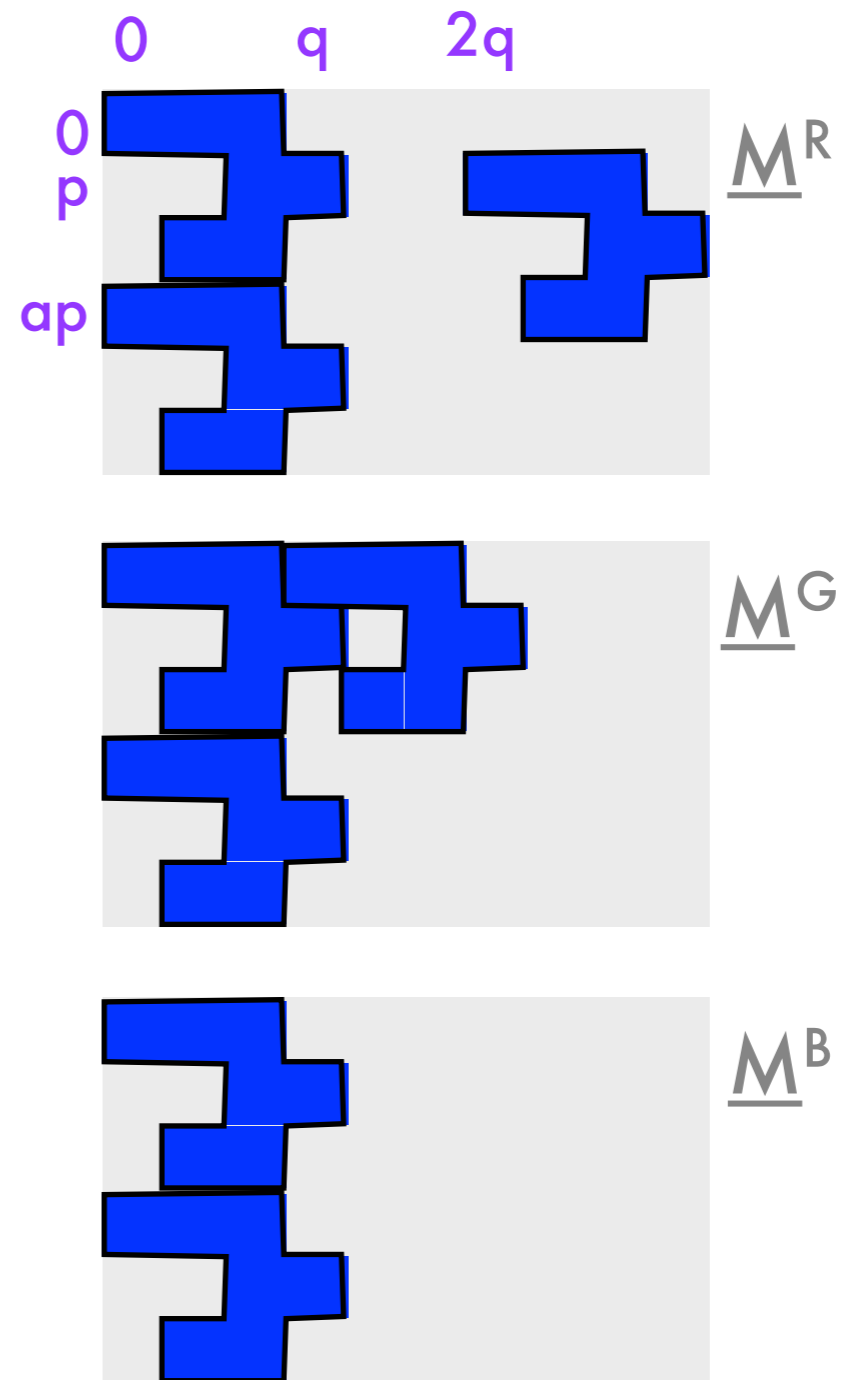

$$a=3$$

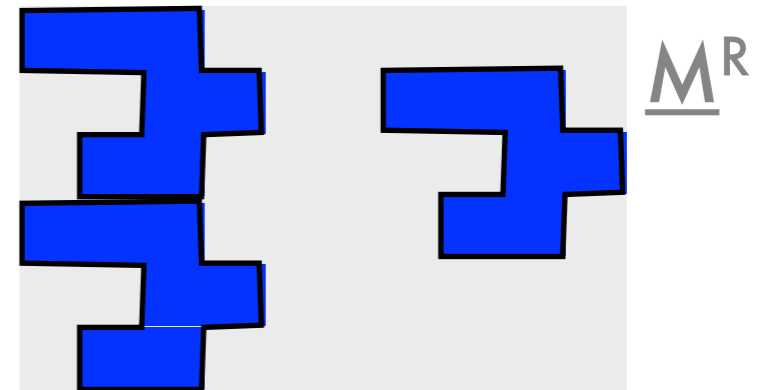

# Example case $b=1, a \geq 2$

- We choose  $k, l$  large enough
- block tilings are as depicted, (R1) ok

# Proving (R2)

- We have to show  
*(R2) Let  $M$  be a solution to the tiling tomography instance obtained by the reduction. Then every block in  $M$  is one of  $\underline{M}^R, \underline{M}^G, \underline{M}^Y$  (or projection-equivalent)*
- There might be another block tiling in the solution, namely  $\underline{M}^A$
- It counts like  $\underline{M}^R$  in the column projections and like  $\underline{M}^G$  in the row projections
- Since total row projections equal total column projections this is impossible

# Perspectives

- What about approximation algorithms?
- What about complete tilings, for a constant number of tiles?
